Malnutrition Care during the COVID-19 Pandemic: Considerations for Registered Dietitian Nutritionists

Abstract

Recent evidence examining adults infected with COVID-19 has indicated a significant impact of malnutrition on health outcomes. Individuals who have multiple comorbidities, are older adults, or who are malnourished are at increased risk of being admitted to the intensive care unit and of mortality from COVID-19 infections. Hence, nutrition care to identify and address malnutrition is critical in treating and preventing further adverse health outcomes from COVID-19 infection. This document provides guidance and practice considerations for Registered Dietitian Nutritionists (RDNs) providing nutrition care for adults with suspected or confirmed COVID-19 infection in the hospital, outpatient, or homecare settings. In addition, this document discusses and provides considerations for RDNs working with individuals at risk of malnutrition secondary to food insecurity during the COVID-19 pandemic.

1 **Malnutrition Care during the COVID-19 Pandemic: Considerations for Registered** 2 **Dietitian Nutritionists**

3 **Abstract**

4 Recent evidence examining adults infected with COVID-19 has indicated a significant impact of
5 malnutrition on health outcomes. Individuals who have multiple comorbidities, are older adults,
6 or who are malnourished are at increased risk of being admitted to the intensive care unit and of
7 mortality from COVID-19 infections. Hence, nutrition care to identify and address malnutrition
8 is critical in treating and preventing further adverse health outcomes from COVID-19 infection.
9 This document provides guidance and practice considerations for Registered Dietitian
10 Nutritionists (RDNs) providing nutrition care for adults with suspected or confirmed COVID-19
11 infection in the hospital, outpatient, or homecare settings. In addition, this document discusses
12 and provides considerations for RDNs working with individuals at risk of malnutrition secondary
13 to food insecurity during the COVID-19 pandemic.

14 **Introduction**

15 Medical Nutrition Therapy (MNT) plays an important role in the prevention and treatment of
16 malnutrition. There is significant evidence to demonstrate that protein-energy malnutrition from
17 inadequate dietary intake can increase risk of infectious diseases.¹ Reciprocally, any exposure,
18 including infectious disease, that impairs immune function and causes malabsorption, increased
19 catabolism, or decreased nutrient intake can increase risk of malnutrition. Exploratory studies
20 indicate that patients infected with Coronavirus disease of 2019 (COVID-19) experience some
21 or any of the following symptoms: fever, cough, shortness of breath, muscle ache, confusion,
22 headache, sore throat, chest pain, pneumonia, diarrhea, nausea and vomiting, and loss of taste

23 and smell, all of which may influence nutrition status, and, ultimately immune function.^{2,3} The
24 term *malnutrition* is most simply defined as imbalanced intake of protein and/or energy over
25 prolonged periods of time and can occur in both underweight and overweight.⁴ The current
26 document provides guidance that primarily focused on protein-energy malnutrition, which can
27 result from inadequate intake, increased requirements, impaired absorption, and/or altered
28 nutrient utilization.⁵

29 The purpose of this document is to provide general guidance and practice considerations for
30 Registered Dietitian Nutritionists (RDNs) providing care to the malnourished adult in the
31 hospital, outpatient or home care settings during the COVID-19 pandemic, including:

- 32 ➤ Screening and assessment for malnutrition in adults with suspected or confirmed
33 COVID-19 infection;
- 34 ➤ MNT for critical illness in the hospital for adults with suspected or confirmed COVID-19
35 infection;
- 36 ➤ MNT for adults with suspected or confirmed COVID-19 infection managing mild to
37 moderate symptoms at home, including transitioning to home from the hospital; and
- 38 ➤ Adults experiencing increased food insecurity secondary to the COVID-19 pandemic.

39 While there are currently no nutrition guidelines specifically for adults with or at risk for
40 COVID-19 infection, many existing guidelines on the Evidence Analysis Library and from other
41 organizations are still applicable and can be used to provide guidance when working with adults
42 with COVID-19 infection.⁶ However, some adjustments may be required to meet the increased
43 metabolic and functional needs caused by the COVID-19 infection and treatments. The
44 following discussion and guidance are based on best current knowledge and existing guidelines

45 from the Academy of Nutrition and Dietetics (Academy) and other organizations. This document
46 is not exhaustive and there is still much to be learned about the effect of nutrition management
47 on COVID-19 infection and severity.

48

49 **I. Screening and assessment of malnutrition in adults with suspected or confirmed COVID-**
50 **19 infection**

51 It has been well-established that malnutrition is associated with poor health outcomes.⁷ In the
52 context of an infection, such as COVID-19, an individual with malnutrition may have sub-
53 optimal immunity, contributing to a longer or more difficult recovery. Nutrition screening aims
54 to identify patients who are at risk for malnutrition and provide a referral for RDN to deliver
55 detailed nutrition care based on the nutrition care process,⁸ including assessment, diagnosis and
56 intervention by an RDN, in order to treat and prevent further malnutrition and consequent
57 adverse health outcomes.

58

59 **For adults with suspected or confirmed COVID-19 infection, the Malnutrition Screening**
60 **Tool (MST) can be used to identify individuals who are at risk of malnutrition regardless of**
61 **setting.**

62

63 A recent systematic review and corresponding position paper published by the Academy states,
64 “based upon current evidence, the Malnutrition Screening Tool should be used to screen adults
65 for malnutrition (undernutrition) regardless of their age, medical history, or setting.”⁹

66 The MST appears to still be applicable for adults with COVID-19, as it is a quick and easy-to-
67 use validated tool based on two questions addressing decreased intake due to poor appetite and
68 recent unintentional weight loss.¹⁰ Due to limited resources and staff during the COVID-19
69 pandemic, some nutrition screening procedures may require flexibility to better meet safety
70 needs and operational needs of an organization. For example, while nurses or other team
71 members may have conducted nutrition screening prior to the COVID-19 pandemic, during the
72 pandemic, these professionals may be needed for emergency patient care and may not be able to
73 perform malnutrition screening. In these cases, the nutrition team could carry out the screening
74 process so that patients who are at risk for malnutrition can receive appropriate nutrition
75 assessment and intervention without delay. Also, special coordination, such as conducting
76 nutrition screening using patient room telephones, can be considered to minimize staff exposure.

77

78 **For adults with suspected or confirmed COVID-19 infection, the RDN should perform a**
79 **comprehensive nutrition assessment to identify malnutrition regardless of setting.**

80

81 Although there are currently no nutrition guidelines specifically for patients with COVID-19, the
82 Academy's assessment recommendations within evidence-based practice guidelines, available on
83 the Evidence Analysis Library, can be used to guide nutrition assessment for individuals with
84 suspected or confirmed COVID-19.⁶ **Appendix 1** displays some examples of nutrition
85 assessment guidance for critically ill individuals in the five domains: food and nutrition-related
86 history, anthropometric measurements, biochemical data, medical tests and procedures, nutrition-
87 focused physical findings, and client history. Most of these nutrition assessment tools and

88 procedures are applicable to adults with suspected or confirmed COVID-19 infection. For
89 instance, the Subjective Global Assessment can still be used to diagnose nutrition status, and it is
90 important to take medications and IV drips, such as Propofol or Dextrose 5% (D5), into
91 consideration when assessing patients, so nutrition prescription can be adjusted as needed. In the
92 context of the COVID-19 pandemic, touching or gentle palpating the patient to determine muscle
93 and fat store losses may not be possible. In these cases, the RDN can still conduct visual
94 inspection to note indentions and bony prominences which could indicate somatic losses. For
95 RDNs working directly with patients infected with COVID-19, personal protective equipment
96 (PPE) should be used per institution policy while conducting in-person nutrition assessment.
97 RDNs may also utilize nursing and physician notes to provide evidence of wasting as the disease
98 progresses.

99 A comprehensive assessment should result in the RDN determining the nutrition diagnosis.
100 Examples of potential nutrition diagnoses applicable to adults infected with COVID-19 may
101 include malnutrition, increased nutrient needs, predicted inadequate energy intake, altered
102 gastrointestinal function, or inadequate energy intake. Additionally, nutrition assessment can
103 assist in identifying the key etiology of the diagnosis, which will help the RDN determine the
104 best intervention for each patient. For example, an RDN might identify a patient's inability to
105 reach protein and energy needs orally resulting in the need for supplemental oral or enteral
106 nutrition (EN).

107

108 **II: MNT for adults with malnutrition in the intensive care unit (ICU) with suspected or**
109 **confirmed COVID-19 infection**

110 Most patients admitted to the ICU with COVID-19 are acutely malnourished.¹¹ Poor appetite is
111 common with infection, and patients with non-invasive ventilation (NIV) (no endotracheal tube
112 or tracheostomy tube, such as CPAP or BiPAP, often have inadequate intake of calories and
113 protein to meet needs.¹² Critically ill ICU patients should be provided with small frequent
114 feedings including high energy and protein foods and oral nutrition supplements. If protein and
115 energy needs cannot be met with oral intake, nutrition support should be initiated. Though EN
116 is typically the preferred route for nutrition support, airway complications may occur in patients
117 with NIV, and parenteral nutrition may be therefore considered under these conditions.¹³

118

119 **In individuals with suspected or confirmed COVID-19 infection in the ICU who are not**
120 **mechanically vented, RDNs should work with the multi-disciplinary team to ensure**
121 **adequate protein and energy intake. When needs cannot be met orally, enteral nutrition is**
122 **preferred to parenteral nutrition. If enteral nutrition is not appropriate or tolerated,**
123 **parenteral nutrition must be initiated in a timely manner to treat and prevent further**
124 **malnutrition.**

125

126 **EN Initiation**

127

128 **In adults with suspected or confirmed COVID-19 infection in the ICU, RDNs should work**
129 **with the multi-disciplinary team to ensure nutrition support is initiated within 36 hours of**
130 **hospitalization or within 12 hours of intubation.**

131

132 Nutrition support should be initiated as soon as possible, ideally within 36 hours of
133 hospitalization or within 12 hours of intubation.¹⁴ In adults in the ICU, requiring nutrition
134 support, EN should be provided instead of parenteral nutrition (PN) if the patient is
135 hemodynamically stable and has a functional gastrointestinal (GI) track.¹³⁻¹⁵ The RDN should
136 consider holding EN if:

- 137 • Mean Arterial Pressure < 65 mm Hg;¹⁴
- 138 • Escalating number and doses of vasopressors;¹⁴
- 139 • Rising lactate levels;¹⁴
- 140 • Unexplained abdominal pain, nausea, vomiting, diarrhea, abdominal distention;¹⁴
- 141 or
- 142 • Uncontrolled shock, life-threatening hypoxemia, hypercapnia or acidosis.¹³

143 When EN is not feasible or appropriate, PN may be necessary to treat or prevent malnutrition.

144 PN will require management by a multi-disciplinary care team due to high risk for line sepsis and
145 metabolic complications, such as refeeding syndrome and hyperglycemia.

146

147 **EN Administration**

148 EN should initially be provided via a nasogastric (NG) tube or orogastric (OG) tube, since
149 placement of feeding tubes in the small bowel could delay initiation of feeding and could
150 increase risk of spreading infection due to the need for skilled staff and confirmation of feeding
151 tube placement.^{13,14} The height of the bed should ideally be elevated 30 to 45 degrees,¹⁵ and the
152 nasogastric tube size should be a 10-12 french, preferably 12 french to facilitate bolus feeding if

153 necessary.^{14,16} Enteral feeding for patients in prone position is not contraindicated. However, if
154 possible, the height of the bed should be elevated 10-25 degrees.¹⁴

155 If feeding pumps are available, continuous feeding via a feeding pump is recommended.^{14,17} If
156 feeding pumps are not available, the next alternative is a gravity feed. If a gravity feed is not
157 possible, bolus feedings should be provided.¹⁴ Bolus feeds should not be provided to patients
158 with gastric abnormalities nor should they be provided to patients requiring post pyloric
159 feedings.¹⁶ The RDN should develop the bolus feeding and flushing schedule in accordance
160 with fluid restrictions, institutional policies, and how frequently the nurse enters the patient's
161 room to minimize staff exposure to infection.

162

163 **EN Rate and Progression**

164 **In adults with suspected or confirmed COVID-19 infection, RDNs should work with the**
165 **multi-disciplinary team to develop an individualized nutrition prescription based on**
166 **thorough assessment of protein and energy needs to prevent further decline in nutritional**
167 **status.**

168

169 Indirect calorimetry is typically recommended as best practice for estimating energy expenditure.
170 However, indirect calorimetry is not recommended during the COVID-19 pandemic because it
171 requires disconnection from the ventilator circuit and a considerable amount of time, both of
172 which increase risk for COVID-19 transmission to healthcare providers.¹³

173 RDNs should initiate hypocaloric EN feedings and progress to 15-20 kcal/kg actual body weight
174 (ABW) (use ideal body weight (IBW) if BMI >30 kg/m²), or less than 70% of Penn State
175 Equation Estimate¹⁵ within the first week.^{13,14} During the second week, EN should be advanced
176 to 25 kcal/kg ABW; 11-14 kcal/kg ABW if BMI 30-50 kg/m²; and 22-25 kcal/kg IBW if
177 BMI>50 kg/m.^{13,17} Practitioners must account for energy intake from drips and medications, such
178 as Propofol, when determining energy needs from EN. EN should provide 1.2-2.0 gm of protein
179 per kg ABW in patients with normal weight status, and 1.2-2.0 gm/kg IBW if BMI >30
180 kg/m.^{14,17}

181

182 EN Formula and Supplementation

183 **In adults with suspected or confirmed COVID-19 infection, RDNs should take overall**
184 **nutrition assessment including nutrient needs, fluid status, and interventions to address**
185 **fluid status into consideration when selecting the type of EN formula.**

186

187 In adults who are critically ill in the ICU, fluid management is impacted by a multitude of
188 factors, including COVID-19 infection pathology. For the initial resuscitation of patients with
189 COVID-19, physicians are frequently restricting fluid volumes.¹⁸ To further complicate
190 assessment of fluid status, approximately 40% of patients who are critically ill with COVID-19
191 infection are developing acute kidney injury (AKI).¹⁹ The exact cause of AKI in these patients is
192 unknown, however, dehydration starting prior to admission could be a contributing factor.

193 Patients who are critically ill with COVID-19 infection could potentially be receiving a
194 significant amount of energy from drips and medications and, due to high protein needs, RDNs
195 should select high protein formulas ($\geq 20\%$ protein) during the acute phase of the illness. RDNs
196 should evaluate blood urea nitrogen (BUN) and creatinine trends as part of their nutrition
197 assessment and adjust the EN rate and formula as appropriate, though recommended protein
198 intake should not go below 1.2 gm/kg to prevent further catabolism. Immune modulating
199 formulas are another option because, theoretically, they may alter a patient's immune response
200 and clinical outcomes. Unfortunately, consistent high-quality evidence for immune modulating
201 formulas are lacking and, therefore, cannot be formally recommended at this time for patients
202 with COVID-19 infections.^{14,15}

203 Some patients may need additional protein and fiber beyond what is provided in the formula.
204 Once patients are no longer in the acute phase of COVID-19 illness, supplemental protein and
205 fiber should be considered. To reduce staff exposure, supplemental protein and fiber should be
206 provided together along with appropriate flushes.¹⁴ Some patients recovering from COVID-19
207 infection begin to experience diarrhea, at which point a high-fiber formula should be considered.

208

209 **EN Considerations for (NIV)**

210 In patients with NIV, feeding tube placement may be contraindicated due to potential issues such
211 as air leakage, distention of the stomach, or if the patient is in the prone position.¹² Stomach
212 distention can lead to poor feeding tolerance and impaired diaphragmatic function. If NG/OG
213 placement is appropriate, feeding pumps should be prioritized to patients on NIV so they can be

214 fed continuously. If a feeding pump is not available, a gravity drip should be considered. Bolus
215 feeds should not be used in patients with NIV due to increased risk for aspiration.¹²

216

217 **Monitoring and Evaluation**

218 **In adults with suspected or confirmed COVID-19 infection, RDNs should monitor nutrition**
219 **support tolerance daily, and work with the multidisciplinary team to promote tolerance.**

220

221 Tolerance can be evaluated through a physical examination including abdominal distention,
222 diarrhea, and laboratory values. Gastric residual volumes (GRV) should not be used as a sole
223 indicator of EN tolerance. Practitioners should recommend against holding EN when GRV is less
224 than 500 ml in the absence of other signs of intolerance.^{14,15,20} To promote EN tolerance, the
225 RDN should work with the multi-disciplinary team to promote the following initiatives:

- 226 ● Patients beds should be upright at an angle of 30 - 45 degrees (10-25 degrees if
227 prone).
- 228 ● If GRVs between 200-500, consider promotility agents.
- 229 ● If the abdomen remains distended after the above initiatives, consider aspirating
230 the stomach and checking GRV; GRV of < 500ml/6hrs is considered acceptable,
231 repeat after 6 hours if GRV is >500ml.¹⁵
- 232 ● In the event a patient is experiencing diarrhea, soluble fiber supplementation
233 should be provided.^{14,15}

- 234 ● If the patient is still not tolerating EN, consider placement of nasojunal (NJ)
235 tube.¹⁴
- 236 ● If EN is not feasible, PN should be initiated as soon as possible.

237

238 In addition to physical assessment, laboratory values should be monitored daily. RDNs should
239 monitor for refeeding syndrome and hyperglycemia especially amongst patients receiving PN.
240 To monitor for refeeding syndrome, RDNs should monitor sodium and fluid balance and serum
241 phosphorus, potassium, magnesium and calcium, which may decrease rapidly.²¹ If refeeding
242 syndrome is suspected, electrolytes should be immediately replaced intravenously and feeding
243 rate should be decreased.²¹

244

245 **Post-Intubation**

246 Prolonged ICU stay may exacerbate muscle catabolism, and therefore increase protein needs.¹³
247 Furthermore, dysphagia may result from post-intubation trauma, and its presence for a prolonged
248 period can lead to consequences such as aspiration pneumonia and malnutrition.²² The nutrition
249 care plan for these patients should incorporate recommendations from the speech-language
250 pathologist and should accommodate increased nutrient requirements of the patients, food
251 preferences, and availability of resources. If severe dysphagia persists and energy and protein
252 needs cannot be met, the RDN may need to either initiate or resume EN. If EN is not possible,
253 PN should be provided until oral or EN can be resumed.¹³

254

255 **III. MNT for malnutrition in adults with suspected or confirmed COVID-19 infection in**
256 **outpatient and home care settings, including transitioning to home from the hospital**

257 According to studies from China and case reports in the United States, the majority of all
258 COVID-19 patients exhibited mild to moderate symptoms and hence, managed their illness at
259 home.^{3,23} Common symptoms of COVID-19 can lead to problems with nutrient absorption
260 and/or overall inadequate dietary intake. Patients recovering from COVID-19 infection who are
261 discharged from the hospital may still be experiencing COVID-19 symptoms and may be
262 malnourished and, hence, have increased nutrient needs. Therefore, for individuals managing or
263 recovering from COVID-19 symptoms in their homes, maintaining adequate nutrient intake and
264 hydration is critical.

265

266 **In adults with suspected or confirmed COVID-19 infection who are managing their illness**
267 **at home, it is crucial for RDNs to provide remote MNT in order to help achieve or maintain**
268 **optimal nutrition status.**

269

270 **In adults with suspected or confirmed COVID-19 infection who are managing their illness**
271 **at home, RDNs should work with patients and their families to ensure adequate intake of**
272 **energy, protein and hydration.**

273

274 When counseling patients with suspected or confirmed COVID-19 infections who are in their
275 homes or in the outpatient setting, RDNs can advise patients and their families of the following:

- 276 ● Ensure adequate intake of energy and protein by, at minimum, meeting 100% of the
277 recommended dietary allowance for energy and protein based on age and gender. These
278 requirements will likely be increased due to the pathology of COVID-19 infection.
- 279 ● High-calorie, high-protein meals and snacks can help prevent weight loss and maintain
280 lean muscle mass. For example, RDNs can advise eating vegetables with cream, butter,
281 margarine, cheese sauce, olive oil, or salad dressing to increase energy intake and choose
282 foods high in protein, such as milk, eggs, cheese, meats, fish, poultry, nuts, and beans.²⁴
- 283 ● Nutrient-dense foods and beverages including oral nutritional supplements are good
284 methods to increase calorie and protein intake if oral dietary intake is not adequate to
285 meet needs (e.g., protein powders and meal replacement shakes and bars).²⁴
- 286 ● For individuals having difficulty coordinating chewing and breathing, beverages might be
287 a better option to efficiently increase energy intake compared to solid foods.
- 288 ● Micronutrient supplements can help compensate for inadequate oral intake to address
289 deficiencies.²⁴
- 290 ● Manage nausea, vomiting and shortness of breath by offering small, frequent meals and
291 snacks.^{25,26}
- 292 ● Focus on providing foods that require little handling, preparation, or effort to eat.
- 293 ● Ensure adequate intake of fluids to stay hydrated throughout the day and evening. If the
294 patient is suffering from vomiting and diarrhea, advise consumption of rehydration
295 drinks.

296 Additional guidance on managing malnutrition through adequate intake of calories, protein, and
297 hydration can be found in the Academy's Nutrition Care Manual, Evidence Analysis Library,
298 and Malnutrition Quality Improvement Toolkit.^{6,25,27} Besides nutrition management, RDNs

299 should consider discussing guidelines for managing safe home care practices including food
300 safety with patients and their families.^{28,29}

301

302 **IV. Additional Nutrition Considerations for Malnutrition in adults during the COVID-19**

303 **Pandemic**

304 *Adults with Co-morbidities:*

305 While there is no clear evidence demonstrating a causal relationship between COVID-19
306 infection and underlying comorbidities, recent evidence suggests that the majority of severe
307 symptoms and complications from COVID-19 infection are reported among older adults and
308 individuals with underlying comorbidities such as diabetes, chronic kidney disease,
309 cardiovascular disease, or pulmonary disorders.²³ Individuals with these co-morbidities are
310 already at increased risk of malnutrition, which may contribute to an impaired immune system
311 and exacerbation of symptoms. It is imperative that individuals with pre-existing conditions such
312 as chronic kidney disease, cardiovascular disease, hypertension, or pulmonary disorders receive
313 regular nutrition assessment, and individuals at moderate or high risk of malnutrition receive
314 effective nutrition interventions by RDNs. RDNs should ensure that individuals with co-
315 morbidities have adequate oral dietary intake to meet calorie and protein needs, and oral
316 nutritional supplements may be considered to meet needs if dietary intake is inadequate. The
317 COVID-19 pandemic requires that prevention and management of malnutrition become a focus
318 in patient care.

319 The Academy has recent guidelines containing recommendations on malnutrition management in
320 chronic kidney disease, cystic fibrosis, and chronic obstructive pulmonary disease (COPD).^{6,30,31}

321 These guidelines are still relevant to patients with COVID-19 and these conditions; however,
322 implementation of these recommendations should include consideration of COVID-19
323 pathology, PPE standards set by Centers of Diseases Control,²⁹ and institutional guidelines.

324

325 **For adults with existing comorbidities and not infected with COVID-19, RDNs should**
326 **continue to advise consuming a nutrient-dense eating pattern to meet protein and energy**
327 **needs, with oral supplementation when necessary, to prevent and treat malnutrition.**

328

329 **For adults with existing comorbidities and with suspected or confirmed COVID-19**
330 **infection, RDNs should proactively prevent and treat protein-energy wasting by regularly**
331 **assessing weight and nutritional status when possible, and advising adequate protein and**
332 **energy intake through diet, with supplementation through oral, EN or PN when necessary.**

333

334 *Micronutrients:*

335 Among patients at risk or with suspected or confirmed COVID-19 infection, there is a paucity of
336 evidence indicating effects of adding micronutrients through supplementation or intravenously
337 on risk or severity of COVID infection. Therefore, it is critical for RDNs to rely on their
338 scientific training and clinical expertise to determine if the patient is deficient in a specific
339 micronutrient and if treating the respective deficiency is a priority. Existing evidence from
340 critical illness population can also help inform practice for patients with COVID-19 infections.

341

342 V. Malnutrition and Food insecurity during the COVID-19 Pandemic

343 While COVID-19 infection itself may increase risk for malnutrition, food insecurity caused by
344 the economic crisis and social isolation secondary to the COVID-19 pandemic may also increase
345 risk for malnutrition.³² In 2018, 37 million individuals in the US were food insecure.³² Adults
346 with food insecurity are at higher risk of chronic conditions, such as mental health problems and
347 depression, diabetes, hypertension and sleep problems. Children with food insecurity are at
348 increased risk for poor health, asthma, obesity, anemia, developmental problems, behavioral
349 problems and aggression and anxiety.^{33,34}

350 Currently, there have been no major food shortages reported in the US related to the COVID-19
351 pandemic.³⁵ However, unemployment rates have soared,³⁶ causing unprecedented demand for
352 unemployment benefits and several initiatives to reduce the burden of monthly payments for
353 rent, utilities, or home or student loans. Despite these measures, many individuals are struggling
354 economically, which may decrease accessibility of fresh and healthy foods. Social isolation
355 measures implemented to prevent the spread of COVID-19 infection may also increase risk for
356 food insecurity. For example, in the United States, 29.7 million children³⁷ depend on free lunches
357 from the National School Breakfast and Lunch Programs, but during the current COVID-19
358 pandemic, many schools have closed, and clients may be uncertain how to access free meals
359 being provided by schools. Uncertainty of how to access food assistance programs may increase
360 the daily financial burden on low-income families to provide healthy meals. In addition,
361 individuals who are at high risk of severe symptoms and mortality from COVID-19 infection,
362 including individuals who are elderly, may be wary of shopping at the grocery store or may want
363 to avoid public transportation to the grocery store. RDNs working in the community, outpatient,

364 and hospital settings have a crucial responsibility to identify clients' food access needs and
365 provide federal, state, and local resources to help address these needs.

366

367 **When appropriate, RDNs should screen for food insecurity, provide guidance and**
368 **resources for eating healthfully on a budget, and provide resources to improve access to**
369 **healthy foods.**

370

371 When working with individuals with or at risk of malnutrition due to food insecurity during the
372 COVID-19 pandemic, RDNs should consider the following:

373 ● It may be advantageous to screen for food insecurity. Validated tools include the 2-item
374 Hunger Vital Sign tool as well as the United States Department of Agriculture (USDA)
375 screening tool.³⁸⁻⁴⁰

376 ● RDNs can counsel individuals and their families to focus on healthful food choices by
377 providing thrifty meal options with grocery lists and recipes. RDNs can additionally
378 encourage families to reduce their grocery bills by brainstorming methods to decrease
379 food waste.⁴¹⁻⁴⁴

380 ● If possible, RDNs may be able to consult with clients directly in their homes via
381 telehealth. Remote sessions can be an opportunity to reach clients when they are near
382 their cupboards and refrigerators, which may be an effective method of collaborating on
383 dietary changes in real time and place. The Academy provides resources to provide

384 nutrition resources via telehealth during the COVID-19 pandemic.⁴⁵⁻⁴⁸ RDNs should ask
385 clients which communication methods they prefer.

- 386 • RDNs can facilitate connecting individuals with grocery delivery services as well as
387 neighbors, family, and friends to help those infected with COVID-19 get the food they
388 need to prevent and treat malnutrition.

389

390 **For clients and families at risk for food insecurity, RDNs should discuss options to improve**
391 **food access in through federal, state, and local programs.**

392

393 Due to the unprecedented economic crisis caused by the COVID-19 pandemic, several federal,
394 state, and local food assistance programs have developed, enhanced or modified services in order
395 to meet needs. RDNs should assist in connecting clients with available resources.

- 396 • When appropriate, refer clients to a local food bank⁴⁹ or assist them in navigating
397 enrollment in federal food assistance programs or Meals on Wheels.⁵⁰
- 398 • The United States Department of Agriculture (USDA) has provided several “flexibilities
399 and contingencies” for food assistance programs, including the Supplemental Nutrition
400 Assistance Program (SNAP), the Special Supplemental Nutrition Program for Women
401 Infants and Children (WIC) and the National School Lunch and Breakfast Programs, in
402 order to adapt to increased need for these services along with the reduced capabilities of
403 delivering these services directly to clients .⁵¹

- 404 • The USDA’s Food and Nutrition Service responded to the COVID-19 pandemic through
405 efforts to provide school lunches to eligible children when schools are closed through the
406 Summer Food Service Program or Seamless Summer Option,⁵² and RDNs can utilize
407 these tools to assist connecting families with the school lunch program.⁵³
- 408 • The USDA has also provided waivers for WIC requirements to accommodate remote
409 services; WIC food substitution waivers; and provision of emergency food allotments to
410 SNAP households.⁵¹

411

412 **As leaders in nutrition, RDNs should advocate for increased access to healthy foods by**
413 **supporting state and federal initiatives for increased and emergency food assistance.**

414

415 Increased risk of food insecurity during the COVID-19 pandemic requires proactive, broad-scale
416 action to help individuals and families improve or maintain nutrition status, thus preventing even
417 more damage to health from the COVID-19 pandemic. RDNs can affect change on a state and
418 local level through advocacy through the following venues:

- 419 • The Academy’s “Action Center” provides templates for letters to representatives or
420 senators to communicate support or opposition for bills that impact public health. RDNs
421 can “Take Action” by visiting this resource and sending a letter of support to their
422 respective lawmakers to help Americans keep food on the table during the COVID-19
423 pandemic and to urge congress to prioritize federal food assistance program funding.⁵⁴

- 424 ● Monitor the Academy's Action Center to increase awareness and advocacy for food
425 assistance programs as opportunities arise.⁵⁴
- 426 ● "Take Action" and monitor opportunities to support food assistance at the Food Research
427 & Action Center⁵⁵ and the Alliance to End Hunger.⁵⁶
- 428 ● Monitor and utilize advocacy tools provided by the Food Research & Action Center,
429 including to maximize the role of the WIC program to support health and food security.⁵⁷

430 The COVID-19 pandemic has created an unprecedented need for RDNs to assess and address
431 food insecurity among clients and their families through innovative and conscientious nutrition
432 counseling, referral to and participation in food assistance programs, and through taking action to
433 advocate for greater access to food assistance on state and federal levels.

434

435 **VI. Research Needs**

436 In order to inform evidence-based nutrition and dietetics practice for individuals infected with
437 COVID-19, the Academy is seeking to gather data from RDNs who are currently working with
438 patients infected with COVID-19 or whose work has been impacted by the pandemic. In order to
439 inform evidence-based practice, the Academy is seeking to collect patient-level data as well as
440 data at a systems- or process- level using surveillance surveys. The Academy is requesting RDNs
441 register in ANDHII (www.ANDHII.org), which is the Academy's, free, de-identified system for
442 collecting patient-level data, in order to document nutrition care of patients infected with
443 COVID-19. For the patient-level data, the Academy does not specify what, when or how much
444 data RDNs enters into the ANDHII system, but requests practitioners enter data as they have the
445 time and capacity to do so. Collection of this type of patient level data is needed in order

446 elucidate effective interventions to support RDNs in their day-to-day efforts with COVID-19
447 patients and for future pandemics.

448

449 **Conclusion**

450 MNT is an integral aspect of managing malnutrition due to COVID-19 infection. RDNs should
451 proactively implement appropriate nutrition care plans to assess, prevent and treat malnutrition in
452 collaboration with a multi-disciplinary team for individuals with or at risk for COVID-19
453 infection. The guidance provided in this document can assist RDNs in screening, assessing and
454 intervening to prevent and treat malnutrition in patients infected with COVID-19 who are
455 hospitalized or in an outpatient or home care setting and for those at risk for food insecurity
456 secondary to the COVID-19 pandemic. RDNs should work proactively with multi-disciplinary
457 teams and advocate for appropriate and timely nutrition support to effectively improve clinical
458 outcomes and reduce or prevent the adverse consequences of malnutrition in individuals with or
459 at risk for COVID-19 infection.

460

461

462

463

464 **Appendix 1: Nutrition Assessment of Critically Ill Adults adapted from Academy's Critical**
465 **Illness guidelines¹⁵**

CI: Assessment for Critically Ill Patients

The Registered Dietitian Nutritionist's (RDNs) assessment of critically ill adults should include, but not be limited to the following:

Food and Nutrition-Related History:

- History of nutrient intake (energy intake, meal-snack pattern, macro- and micronutrients, etc.)
- Adequacy of nutrient intake/nutrient delivery
- Bioactive substances (alcohol intake, soy protein, psyllium, fish oil)
- Previous and current diet history, diet orders, exclusions and experience, cultural and religious preferences
- Changes in appetite or usual intake (as a result of the disease process, treatment, or comorbid conditions)
- Disease-specific nutrient requirements
- Food allergies/intolerances
- Appropriateness of nutrition support therapy for the patient
- Food and nutrient administration (oral, enteral or parenteral access)
- Physical activity habits and restrictions

Anthropometric Measurements:

- Weight, Height
- Weight change
- Body mass index (BMI)
- Body compartment estimates (fat mass, fat-free mass).

Biochemical Data, Medical Tests and Procedures:

- Biochemical indices (glucose, electrolytes, others as warranted by clinical condition)
- Implications of diagnostic tests and therapeutic procedures (indirect calorimetry measurements, radiography for confirmation of feeding tube placement, other gastrointestinal (GI) diagnostic tests)

Nutrition-Focused Physical Findings:

- Nutrition-focused physical examination that includes, but is not limited to: Fluid assessment, functional status, wound status, clinical signs of malnutrition/overnutrition and/or nutrient deficiencies
- Intake and output (I's and O's) including stool and fistula output, wound drainage
- Existing or potential access sites for delivery of nutrition support therapy
- Abdominal exam
- Fluid status (edema, ascites, dehydration)

- Vital signs.

Client History:

- Medical and family history and comorbidities
- Surgical intervention
- Effect of clinical status on ingestion, digestion, metabolism and absorption and utilization of nutrients
- Indicators of acute or chronic nutrition support-related complications
- Medication management
- Factors that may influence existing or potential access sites for delivery of nutrition support therapy.

Assessment of the above factors is needed to correctly diagnose nutrition problems and plan nutrition interventions. Inability to achieve optimal nutrient intake may contribute to poor outcomes.

Rating: Consensus**Imperative****CI: Reassessment of Critically Ill Adults**

The Registered Dietitian Nutritionist's (RDNs) reassessment of critically ill adults should include:

- Changes in nutrient needs
- A determination of daily actual intake of enteral nutrition (EN), parenteral nutrition (PN) and other nutrient sources
- EN/PN access site
- Changes in clinical status, weight, biochemical data and intake and output (I's and O's)
- Changes in nutrition-focused physical assessment findings.

Rating: Consensus**Imperative**
